

Guard App - API Contract Audit

Introduction

As part of this task, I reviewed all the API modules in the Guard App and checked them against the current backend. The goal was to make sure every API call the app makes matches a real backend route, and to flag any mock data, wrong paths, or mismatched fields. This is important because if the app calls an endpoint that does not exist or sends the wrong data, that feature will fail when it talks to the real backend.

How I checked

I went through each module in `guard_app/src/api` one by one. For every call I compared the method, the path, and the fields against the backend routes in `app-backend/src/routes`. The table below shows the result for each module, and after it I explain the problems that need follow-up.

Module check results

Module	Calls	Backend match	Status
attendance	POST /attendance/checkin/:shiftId, POST /attendance/checkout/:shiftId, GET /attendance/:userId	All exist	OK
auth	POST /auth/register/guard, POST /auth/login, POST /auth/verify-otp, GET /users/me	All exist	OK
shifts	GET /shifts, GET /shifts/myshifts, PUT /shifts/:id/apply	All exist	OK
messages	GET /messages/inbox, /sent, /conversation/:userId, POST /messages, PATCH /messages/:id/read	All exist	OK
notification	GET /notifications, /unread-count, /:id, POST /notifications, PATCH /read-all, /:id/read	All exist	OK
profile	GET /users/me, PUT /users/me	All exist	OK
pushTokens	POST /users/push-token	Exists	OK
guardScore	GET /users/guards/:id/score	Exists	OK
home	GET /users/me, GET /shifts/myshifts (with ?date=)	Paths exist, but ?date= and array handling have issues	Needs fix
payroll	GET /payroll, GET /payroll/export	Path exists but export call is missing a required param	Needs fix
availability	POST /availability, GET /availability/:userId + 4 slot calls	Base calls exist, slot calls do not exist on backend	Needs backend work
sos	/sos/trigger, /sos/:id/location, /note, /cancel, GET /sos/:id	Running on mock data, and real paths are wrong	Needs fix

Problems found

1. Availability slot endpoints do not exist on the backend

availability.ts calls four calendar-slot endpoints:

- POST /availability/slots
- GET /availability/slots/my-slots
- DELETE /availability/slots/:id
- DELETE /availability/slots/clear-all

The backend only has POST /availability, GET /availability/:userId, and PATCH /availability/status. None of the slot routes exist, so these calls will fail with 404. This gap must be raised with the Backend team.

2. SOS module is on mock data and uses wrong paths

sos.ts has USE MOCK_SOS = true, so all SOS actions return fake data, not the backend. The real (non-mock) paths in the file are also wrong: it calls /sos/trigger, /sos/:id/location, /sos/:id/note, /sos/:id/cancel, GET /sos/:id. The backend SOS routes live under /emergency: POST /emergency/sos, GET /emergency/sos, PUT /emergency/sos/:id. The backend also does not have per-alert location/note/cancel or a guard status-poll route, so the feature set does not match.

3. Payroll CSV export is missing a required query param

exportPayrollCsv builds the URL with startDate, endDate, periodType only. The backend GET /payroll/export requires a format param (csv or pdf). Without it the export will fail. Fix: add format=csv, or call the dedicated GET /payroll/export/csv route.

4. home.ts uses an unsupported query param and unsafe array handling

- getTodayShifts sends GET /shifts/myshifts?date=..., but the backend only supports ?status=past. The date filter is ignored, so it does not return today's shifts only.
- getUpcomingShifts calls data.filter(...) directly and assumes the response is an array. Other modules (like shifts.ts) normalize the response first. If the backend wraps the list in an object, this breaks.

5. availability upsert sends the wrong field name (minor)

upsertAvailability sends userId in the body, but the backend reads the field as user. For a guard using their own token this still works (the field is ignored), but the names should match to avoid confusion.

Conclusion

7 of 12 modules match the backend cleanly. Availability slots is the main gap and must be requested from Backend. SOS needs real endpoints and correct paths. Payroll export and home have smaller fixes. All issues are logged as follow-up tickets.
